#### Abstract

The design and development of a mobile application system especially suited for mining industry maintenance management. The system was created to solve typical issues in mining operations, like equipment failures, ineffective maintenance plans, and poor communication between operators and maintenance crews.

This app is designed to streamline the assignment of maintenance tasks within mining operations, enhancing efficiency and communication.

Administrators can easily allocate jobs to employees based on skill sets, availability, and location, ensuring optimal resource utilization. The app features real-time notifications, progress tracking, and comprehensive reporting tools to monitor job status and employee performance. By integrating these functionalities, the application aims to minimize downtime, improve safety standards, and increase overall productivity in the mining sector. Chatti, M. A., & Ziegler, J. (2017)<sup>[7]</sup>

The proposed mining maintenance mobile application revolutionizes the traditional maintenance management

system by enabling seamless job allocation and tracking for administrative staff.

Features including digital work orders, fault diagnostics, predictive and preventative maintenance alerts, and real-time monitoring are all integrated into the mobile application. Through intuitive user interfaces, it facilitates the easy tracking and administration of mobile machinery and equipment while offering extensive information on equipment performance, maintenance history, and downtime. To accommodate distant mining locations with spotty internet, the application also offers offline functionality. Elsayed, T., & Ramadan, H. (2020)<sup>[11]</sup>

The application's efficacy in improving asset reliability and streamlining maintenance work scheduling has been confirmed through case studies and field testing. The study ends by providing insights into the application's potential future developments, such as machine learning-based improvements for predictive maintenance and more features for extensive mining operations. Bello, O., Zeadally, S., & Badra, M. (2017)<sup>[5]</sup>

**Keywords:** Mobile Application, Equipment, Zambia

#### Introduction

For continuous production and safety, the mining sector is highly dependent on the effective operation of machinery and equipment. However, because of the difficult working conditions, high usage, and remote locations of many mining operations, maintaining the operational health of this equipment is a considerable task. Equipment failure-related downtime can lead to significant financial losses and delays in operations.

A viable answer to these problems is the use of contemporary technology in the form of a mobile application system for maintenance management. By providing real-time monitoring, predictive maintenance, and simplified communication between maintenance teams and equipment operators, mobile applications have the potential to completely transform the scheduling, tracking, and execution of maintenance operations. These solutions have the potential to greatly lower unscheduled downtime, increase equipment dependability, and streamline maintenance procedures, all of which can boost mining operations' productivity and cut costs. Cai, G., & Lai, C. (2020)<sup>[6]</sup>. *Smart mining and maintenance of equipment: A review. Journal of Mining and Mechanical Engineering*, 40(1), 7-17.

## Background

The Zambian economy mostly depends on copper. This implies that the mining industry is the one priority industry of the country. Because it makes a substantial contribution to the supply of raw commodities including metals, minerals, and energy supplies, the mining sector is vital to the growth of the world economy. However, mining activities are frequently carried out in hostile environments, high pressure settings, and distant locales. Maintaining the machinery and equipment required for continuous and secure manufacturing is made extremely difficult by this. *Asadi, E., & Habibi, S. (2021) [3]. Condition-based monitoring and predictive maintenance in mining industry. International Journal of Mining Science and Technology, 31(5), 786-797.*

One of the most important parts of mining operations is maintenance since equipment failure can result in operational downtime, which has a direct effect on profitability and productivity. The conventional method of maintenance, which is frequently predicated on planned preventive or reactive maintenance, is growing less and less effective. Costly downtime is frequently the result of reactive maintenance, which fixes equipment after it breaks. Even while it helps reduce some unplanned failures, preventive maintenance can nevertheless result in wasteful resource consumption because it involves needless maintenance on equipment that is already operating properly.

## Problem Statement

In the mining sector, where production output, cost control, and worker safety are all directly impacted by the operating effectiveness and safety of heavy gear, effective maintenance management is essential. Frequent equipment failures, unplanned downtime, and higher maintenance costs can result from the harsh conditions under which mining equipment operates, frequently in isolated and difficult areas. The needs of contemporary mining operations cannot be met by traditional maintenance methods, which are mostly reactive or time-based.

Many mining businesses currently handle their maintenance responsibilities using antiquated software systems or manual techniques. These ineffective and human error-prone techniques lead to neglected maintenance plans, postponed repairs, and insufficient equipment health monitoring. Furthermore, poor communication between equipment operators and maintenance teams frequently results in improper work order management and delayed reactions to equipment breakdowns. These challenges are made worse by the absence of real-time monitoring and data analytics, since possible equipment concerns are sometimes only discovered after a breakdown occurs, resulting in costly repairs and prolonged downtime. *Gonzalez, M., & Lopez, R. (2018) [15]*

A mobile application solution that enables predictive maintenance, real-time monitoring, and efficient communication between maintenance staff, equipment operators, and management is desperately needed to address these issues. To guarantee constant access to vital maintenance data, wherever one may be, this system should have user-friendly interfaces, function both online and offline, and link easily with IoT sensors and cloud-based data storage.

*Alsayed, Z., & Barakat, S. (2019) [2]. Mobile application development methodologies and frameworks. International Journal of Computer Science and Mobile Computing, 8(12), 15-24*

## Objectives

This study's major goal is to create a mobile application system that uses effective communication tools, real-time monitoring, and predictive analytics to enhance maintenance operations in the mining sector. The application aims to improve overall operational efficiency of mining operations, minimize equipment downtime, and streamline maintenance procedures.

## General Objective

In order to decrease equipment downtime, increase operational efficiency, and lower maintenance costs, the overall goal of this study is to design and develop a mobile maintenance management system for the mining sector that enables predictive maintenance, real-time equipment monitoring, and simplified communication.

## Specific Objection

To analyze the current challenges in maintenance management within the mining industry: Investigate the limitations of existing maintenance systems and identify key areas that require improvement, such as equipment downtime, manual processes, and communication gaps.

To design and develop a mobile application system for real-time monitoring and predictive maintenance:

Create an integrated system that collects real-time data from mining equipment through IoT sensors and generates predictive maintenance alerts to anticipate potential failures.

To implement an offline functionality for remote mining operations: Ensure the mobile application can function in areas with limited or no internet connectivity by allowing maintenance teams to log tasks and access essential data offline, with automatic synchronization when connectivity is restored.

## Scope of the Project

The design and implementation of a mobile application system for overseeing maintenance activities in the mining sector is the major objective of this project. The system's goals are to increase overall operating efficiency, decrease equipment downtime, and simplify maintenance procedures. The study's scope covers a number of important issues, which are explained below:

### Architecture and Design of Systems

The technical architecture and conceptual design of the mine maintenance mobile application system will be covered in the study. This entails outlining the essential features and capabilities, like digital work order management, predictive maintenance alerts, and real-time equipment monitoring. Modern technologies like cloud computing for data storage and accessibility and the Internet of Things (IoT) for real-time data collection will be incorporated into the system's design

Development of Core Features: The research will concentrate on creating specific functionalities that address the particular maintenance challenges faced by the mining industry.

These core features include:

**Predictive Maintenance:** Automated scheduling of maintenance tasks based on equipment usage and historical data to prevent unexpected breakdowns.

**Real-Time Monitoring:** Integration with IoT sensors to provide real-time updates on the performance and condition of critical mining equipment.

**Predictive Maintenance:** Using data analytics to predict equipment failures before they occur, allowing for proactive maintenance.

**Work Order Management:** Creation and tracking of digital work orders, allowing maintenance teams to effectively manage tasks and document maintenance activities.

### Functionality Offline

The investigation will make sure the mobile application can work offline because a lot of mining operations are carried out in isolated locations with spotty or restricted internet access. This includes the capacity to record maintenance activities, monitor the functionality of equipment, and synchronize data after the connection has been restored.

### Interface and Experience for Users.

To make the program easy for users—especially maintenance teams that might lack sophisticated technical knowledge—the scope will also involve designing an intuitive user interface. To support field operations, the system will be customized for tablets and mobile devices.

### Validation and Testing.

To verify the efficacy of the mobile application, the study will test it in actual mining settings. In order to assess the system's effectiveness in lowering equipment downtime, increasing maintenance efficiency, and improving communication between maintenance teams and equipment operators, field tests are conducted on mining sites.

### Security and Data Management.

The administration of the data produced by the mobile application will also be included in the study. This involves storing user-generated work orders, maintenance logs, and equipment performance data securely in a cloud-based setting. By following industry best practices for data security, the study will guarantee the protection of all critical operational data.

## 1. Planning and Requirement Analysis

1. Stakeholder Consultation:
  - Meet with mine operators, maintenance teams, and management to understand their needs.
  - Identify pain points in the current maintenance process.
  - Define key features (e.g., equipment logs, alerts, performance analytics).
2. Requirement Documentation:
  - Document functional and non-functional requirements (e.g., offline functionality, rugged design, etc.).

## 2. Research and Feasibility Study

1. Technical Feasibility:
  - Evaluate hardware compatibility (e.g., rugged mobile devices).
  - Identify integration needs with existing systems like ERP or CMMS software.

2. Market Research:
  - Analyze existing solutions to identify gaps and opportunities for differentiation.
3. Risk Analysis:
  - Assess challenges like poor connectivity in remote areas, data security, and battery optimization.

## 3. Conceptual Design

1. Wireframing and Prototyping:
  - Create low-fidelity wireframes to visualize app layout and user flow.
  - Develop a clickable prototype to validate design concepts with stakeholders.
2. User Feedback:
  - Conduct user testing on prototypes to gather insights and iterate designs.

## 4. Technical Design

1. Architecture Design:
  - Decide on the app architecture (e.g., native or cross-platform).
  - Define backend infrastructure (cloud-based or on-premise).
2. Database Design:
  - Plan the data structure for tracking equipment details, maintenance schedules, and work orders.
3. API Design:
  - Define APIs for data exchange between the app and backend systems.

## 5. Development

1. Frontend Development:
  - Develop the user interface (UI) based on finalized designs.
  - Ensure the app is responsive and intuitive.
2. Backend Development:
  - Build server-side functionality, including APIs, data processing, and user authentication.
  - Implement data synchronization for offline access.
3. Testing During Development:
  - Conduct unit tests to ensure each component functions correctly.

## 6. Testing and Quality Assurance

1. Functional Testing:
  - Verify all features meet requirements.
2. Field Testing:
  - Test the app in actual mining environments for usability and robustness.
3. Security Testing:
  - Validate data encryption and secure communication protocols.

## 7. Deployment

1. Pilot Deployment:
  - Release the app to a small group of users for feedback.
2. Full Deployment:
  - Roll out the app across the organization after addressing feedback from the pilot phase.
3. App Store Release (if applicable):
  - Publish the app on platforms like Google Play and Apple App Store for external users.

## 8. Training and Documentation

1. User Training:
  - Provide training sessions for maintenance staff and operators.
2. Documentation:
  - Deliver user manuals and troubleshooting guides.

## 9. Post-Deployment Support

1. Monitoring and Bug Fixes:
  - Monitor app performance and resolve issues promptly.
2. Updates and Improvements:
  - Regularly release updates based on user feedback and evolving needs.

## 10. Continuous Feedback and Iteration

- Establish feedback loops with users to continually refine the app.
- Use analytics to monitor app usage and optimize features.

## Research Questions

The study seeks to address the following key research questions related to the design and development of a mobile application system for mining maintenance:

1. **What are the current challenges and limitations faced by mining companies in maintaining their equipment?**
  - How do existing maintenance practices contribute to equipment downtime, inefficiency, and increased operational costs?
  - What are the communication and coordination challenges between maintenance teams and equipment operators?
2. **How can a mobile application system improve the efficiency of maintenance management in mining operations?**
  - What features and functionalities are necessary to enhance real-time monitoring, predictive maintenance, and work order management?
  - How can the system be designed to accommodate both online and offline environments, particularly in remote mining locations?
3. **What impact will the integration of predictive maintenance have on reducing equipment downtime and repair costs?**
  - How can real-time data from IoT sensors be used to predict equipment failures and schedule preventive maintenance?
  - What measurable improvements can be expected in terms of reduced downtime, extended equipment life, and overall maintenance efficiency?
4. **How can the mobile application system improve communication and coordination among maintenance personnel, equipment operators, and management?**
  - How effective are mobile-based communication tools (instant messaging, task updates, report sharing) in reducing delays and miscommunication in maintenance workflows?
5. **What are the security and data management challenges involved in implementing a mobile maintenance system in the mining industry?**
  - How can data generated from real-time monitoring

and maintenance logs be securely stored and accessed?

- What are the best practices for ensuring data privacy and protection in cloud-based environments for mining operations?
6. **What is the potential impact of the mobile application system on maintenance costs and overall productivity in the mining sector?**
    - How can the system contribute to minimizing downtime and reducing maintenance-related expenses?
    - What are the long-term benefits of adopting a mobile maintenance system in terms of operational efficiency and equipment reliability?
  7. **How scalable is the mobile application system for use in different mining environments and other industries?**
    - Can the system be adapted to suit different types of mining operations (e.g., open-pit, underground) and other industries that rely on heavy machinery?

## Literature Review

The design and development of a mobile application system specifically aimed at improving maintenance management in the mining sector is presented in this study. Because the mining industry mostly depends on big, complicated equipment that works in challenging conditions, efficient maintenance is essential to maintaining cost control, operational effectiveness, and safety. Conventional maintenance systems frequently suffer from inefficiencies including postponed repairs, poor communication, and a dependence on manual procedures, which can result in unscheduled downtime and higher operating expenses.

Because the mining sector depends so heavily on big, costly, and complicated machinery, efficient maintenance is essential to both cost control and operational effectiveness. Numerous studies highlight the necessity of proactive maintenance techniques to lower equipment downtime and increase machinery longevity. Due to the high expense of unscheduled downtime and the possible safety hazards, traditional maintenance techniques like reactive maintenance repairing equipment after failure are becoming less and less effective. *Chen, Z., Xu, L., & Shi, P. (2019)*<sup>[8]</sup>. *IoT-based remote monitoring and fault diagnostics in mining machines. IEEE Transactions on Industrial Informatics, 15(5),2937-2946.*

Preventive and predictive maintenance are the key topics of recent maintenance management trends. Predictive maintenance uses data-driven methods to forecast when equipment is likely to fail, enabling just-in-time maintenance, whereas preventive maintenance is carrying out routine, scheduled maintenance to avoid equipment failures. Both strategies are essential for reducing unplanned malfunctions and enhancing mining equipment dependability. However, research shows that a lack of real-time data and efficient communication networks prevents many mining operations from completely implementing these tactics.

The study by *Emmanouilidis, C., & Taisch, M. (2018)*<sup>[12]</sup>. In recent years, the idea of predictive maintenance (PdM) has drawn a lot of interest, particularly with the development of Industry 4.0 technologies. PdM uses sensors to gather data from equipment and analytics to forecast potential failure times. For this process, Internet of Things (IoT) sensors are

crucial since they allow for the real-time recording of data like pressure, temperature, and vibration.

According to one study on mobile apps' use in the manufacturing industry, mobile-based maintenance systems decreased machine downtime by 25% and enhanced reaction times by 30%. Similar advancements are expected in the mining industry, where mobile applications can assist in resolving issues pertaining to the necessity for real-time data access and the remote nature of operations. Ghods, A., & Lim, S. (2019)<sup>[14]</sup>. *Mobile technology in asset management: A case study in the mining industry. Journal of Mobile Engineering*, 6(1), 49-56.

### Methodology

In this sector, we used a combination of methods to understand how advanced technologies are used in mining industry and what effects they have. We gathered quantitative data through surveys with miners in different areas and qualitative data from detailed interviews and case studies. We looked at how many miners use these technologies, how they help improve operations, and their impact on costs. We used statistical tools to analyze the survey data and identified common themes in the interview responses. This approach helped us clearly see the benefits and challenges of using new technologies in mines..

### Data Gathering

The kansanshi copper and gold mine: Our main research took place there, a big mine located in North Western. This mine operates on a large scale with a well-organized system covering everything from extracting copper to selling by product. They handle not just local sales but also export their products. the mine has several specialized departments like blustering, transportation, cleaning, finance, distribution, recording, and security.

### Method of Data Collection

The following methods were employed to collect data for this project, ensuring a comprehensive understanding of the mine operations and the challenges faced:

#### Interview Method

Step 1: Preparation of Interview Questions - Developed targeted questions to gather insights into mine management and maintenance challenges.

Step 2: Conducting Interviews - Conducted face-to-face interviews with miner staff to collect detailed information on their experiences and the difficulties they encounter, especially regarding maintenance and equipment management and documentation.

Step 3: One-on-one interviews with key stakeholders, including maintenance managers and IT support teams, were conducted to gain insights into specific operational inefficiencies and potential barriers to the application's adoption.

Step 4: Data Recording - All responses were carefully recorded, and detailed notes were taken to capture comprehensive insights during the interviews.

#### Observation Method

Step 1: Observational Checklist - Created a checklist to systematically observe the manual processes used by staff, particularly in record-keeping downtime and working hours.

Step 2: On-Site Observation - Direct observations of

maintenance processes were made to understand workflows, the time taken for various tasks, and on-site environmental factors affecting equipment and staff.

Step 3: Data Compilation - Organized the observations into a structured format to facilitate analysis and interpretation.

### Focus Group Discussions

Step 1: Formation of Focus Groups - Selected groups of mine workers based on their roles to gather diverse perspectives.

Step 2: Moderating Discussions - Facilitated discussions to probe deeper into the collective experiences and views regarding mines operations and technology use.

Step 3: Synthesis of Information - Recorded and later analyzed the discussions to identify prevalent themes and unique opinions among the group members.

### Survey Method

Step 1: Survey Design - Designed a comprehensive survey with a mix of multiple-choice and open-ended questions to capture a wide range of data regarding mine operations.

Step 2: Distribution and Collection - Distributed the surveys to a broader group of mine staff to ensure a representative sample of responses.

Step 3: Data Analysis - Compiled and analyzed the survey results to quantify the extent of operational issues and to gain a statistical overview of the mine's challenges. To understand how the mines operates and what challenges it faces, I used a mix of interviews, observations, focus groups, and surveys. I talked directly with the mining staff mostly from the maintenance department to hear about their experiences and noted down issues, especially around how they manage downtime and records. I also watched how things are done day-to-day on the mine to see these challenges in action. Through focus groups, I gathered deeper insights from different groups of employees to get a broader view of their daily operations and attitudes when the machine go under down time. Lastly, I sent out surveys to a larger group of staff to get a clearer picture of common problems and collect some hard numbers on how the mine operates. Ghods, A., & Lim, S. (2019)<sup>[14]</sup>.

All this data will be pieced together to paint a full picture of what's happening on the mine and help figure out how to solve these issues and how the mining maintenance mobile app can help to resolve the challenges and improve the production.

### Problems of Existing Procedure

Here are some of the problems that the current farms face:

**Inaccuracy and Errors:** Manual data entry is prone to human errors, which can include typos, misrecordings, or omissions. These mistakes can lead to significant discrepancies in records, affecting everything from inventory management to financial reporting.

**Time-Consuming Processes:** Reactive Maintenance, the predominant approach to maintenance is reactive rather than preventive, with repairs carried out only after equipment failure. This approach results in higher downtime and unplanned expenses

**Need for Real-Time Monitoring:** Maintenance staff and managers highlighted the need for real-time updates on equipment status to proactively address issues and enhance team response. Chatti, M. A., & Ziegler, J. (2017)<sup>[7]</sup>

**Mobile Accessibility:** Technicians in the field expressed

interest in having mobile access to work orders, equipment history, and inventory data, facilitating quicker decision-making and reducing response times.

**Predictive Maintenance Features:** There is a strong interest in predictive maintenance capabilities, such as automated alerts, which can allow teams to anticipate potential failures and schedule preventive interventions.

**High Maintenance Costs:** Reactive repairs are costly, requiring emergency labor, premium charges for expedited spare parts, and occasionally, third-party technical assistance.

**High Equipment Downtime:** On average, equipment experiences downtime of up to 15% of operational hours, significantly impacting productivity. Causes include mechanical failures, delays in repair part availability, and extended repair durations due to insufficient maintenance planning.

**Resource Constraints:** Maintenance teams reported frequent challenges with access to spare parts, specialized tools, and sufficient labor, leading to further delays.

**Communication Delays:** Poor communication between departments results in misaligned maintenance scheduling, ineffective task prioritization, and delayed response to critical issues.

**Safety Incidents:** Unplanned breakdowns have been associated with increased safety incidents, with machinery failures occasionally leading to workplace accidents or hazardous situations for the maintenance crew.

### Purpose of the New System

The purpose of the proposed mining maintenance mobile app management system is to streamline operations, enhance accuracy, and improve access to critical data through mobile. By bringing mobile application in the maintenance sector, paper-based methods will fully wiped off with a digital solution, the system aims to solve several prevalent issues:

**High Equipment Downtime Costs:**

A single piece of equipment failure in mining can cause production to stop for hours or even days, costing the company a lot of money. These losses could be significantly decreased by a system that effectively schedules maintenance and anticipates problems.

**Enhanced Complexity of Operations:**

Large fleets of mobile and stationary machinery are used in modern mining operations, and each one needs to be maintained on a regular basis to operate at its best. As the size and complexity of operations increase, it becomes more and more impractical to manage the maintenance of these devices manually or with antiquated technologies.

**Developments in Predictive Maintenance Technology:** The development of systems that can both anticipate possible problems before they happen and continuously monitor equipment status is made possible by advancements in predictive analytics, the Internet of Things, and mobile technologies. This makes it possible for a more proactive maintenance strategy, minimizing unplanned malfunctions, and streamlining maintenance plans.

Real-time and remote solutions are required:

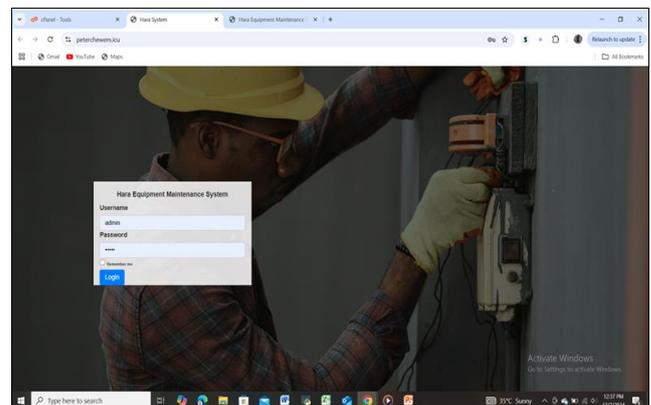

Numerous mining operations are situated in isolated locations with little access to expert assistance on-site. These operations would greatly benefit from a mobile application that works offline and online and provides real-time monitoring and maintenance updates. This would allow for more responsive maintenance procedures and better decision-making.

**Safety and Environmental Aspects:**

Improved safety and environmental compliance in mining operations are also facilitated by routine and effective maintenance. Equipment that is properly maintained lowers the chance of mishaps and lessens environmental effects including oil spills, equipment malfunctions, and unscheduled stoppages. Al-Turjman, F., & Baali, I. (2020) [1].

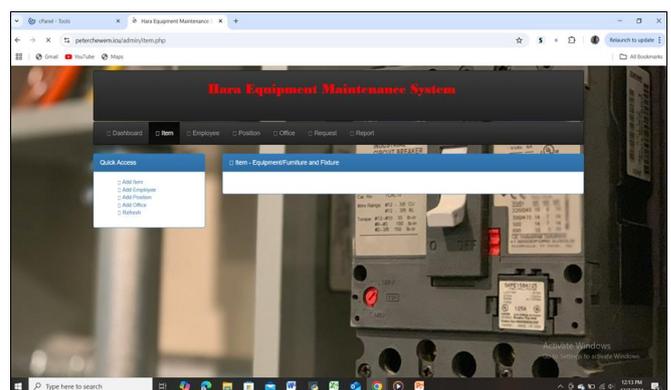

### Functional and Non-Functional Requirements

The project's system is designed to meet the rigorous demands of mining maintenance management through a series of robust functional and non-functional requirements. Here's an expansion of these requirements:

Source: Author

Figure: Login page

Source: Author

Figure: Item page

### 64 Functional Requirements

The system will encompass a comprehensive suite of features tailored to enhance the management of maintenance:

operational metrics, mines can identify cost-saving opportunities, reduce waste, and significantly enhance productivity.

**Disadvantages**

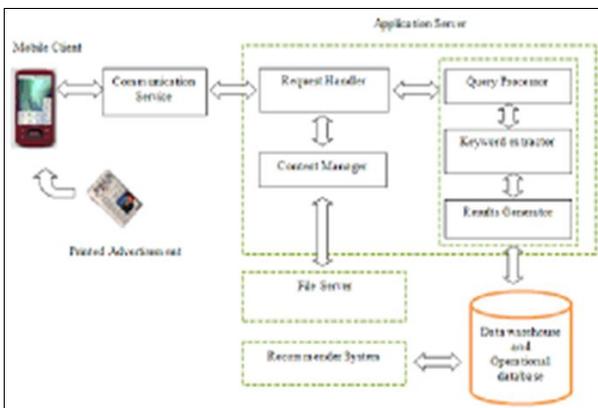

**Initial Setup Costs:** While the long-term benefits are significant, the initial outlay for software and hardware can be substantial. This cost includes purchasing the necessary technology, setting up infrastructure, and potentially upgrading existing systems to be compatible with the new software. These expenses might be prohibitive for smaller or financially constrained miners.

**Training Requirements:** To fully harness the capabilities of the new system, miners from the maintenance and drivers will need to undergo training. This process involves not only learning how to use the system effectively but also understanding how to interpret the data it provides. The time and resources invested in training can be substantial, depending on the complexity of the system and the existing technological proficiency of the staff.

**Customization Needs:** No two mines are exactly alike, despite them falling under open pit mine. each has its specific challenges, requirements, and goals. Consequently, a one-size-fits-all approach is often not feasible, requiring the system to be customized to each mine’s particular needs. Customization can add layers of complexity to the implementation process and increase the overall cost of the system, both in terms of development and maintenance.

**System Design**

The diagram below show the flow charts that will show how the application will function

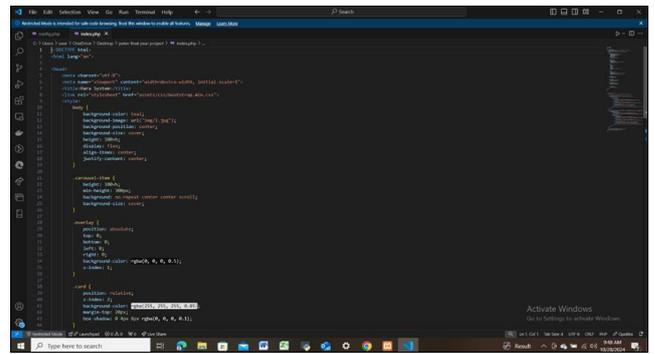

**System Architecture.**

The architecture of the mining maintenance mobile application system comprises several layers, each serving a specific function:

**Presentation Layer:** This layer features the user interface (UI) accessible on mobile devices, designed for intuitive navigation, easy data entry, and offline accessibility.

**Application Layer:** Contains the core application logic, including work order processing, real-time updates, notifications, and predictive maintenance algorithms.

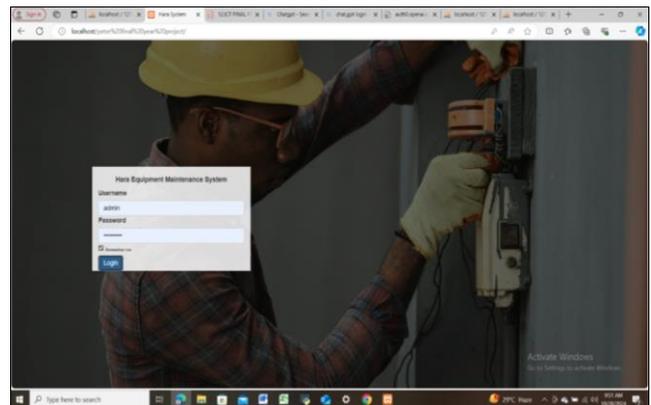

Source: Author

Figure: Application Layer Codes

**Data Management Layer:** Handles data storage and retrieval, utilizing local databases for offline storage and a central database for real-time data sync when connectivity is available.

**Integration Layer:** Allows data exchange between the application and existing ERP or asset management systems, ensuring a centralized data repository and accurate reporting.

**Security Layer:** Provides data encryption, user authentication, and role-based access controls for data protection and secure access.

Source: Author

Figure: login page

**System Class Design**

Each system component has specific responsibilities, ensuring smooth operation within mining sites and compatibility with remote and harsh environmental conditions. Key components are as follows:

**a. User Interface (UI)**

- **Technology:** Android Studio and Visual Studio Code (for Android compatibility).
- **Design Goals:** Ensure high usability and accessibility with minimal navigation complexity.
- **Features:**
  - Work order dashboard
  - Equipment status tracking
  - Offline task creation and data syncing

**b. Work Order Management**

- **Purpose:** Manage maintenance tasks from creation to completion.
- **Features:**
  - Create, assign, and close work orders.
  - Record equipment details, priority levels, and estimated repair times.
- **Interaction:** Data flows from users (maintenance staff) through UI forms to the backend server via APIs.

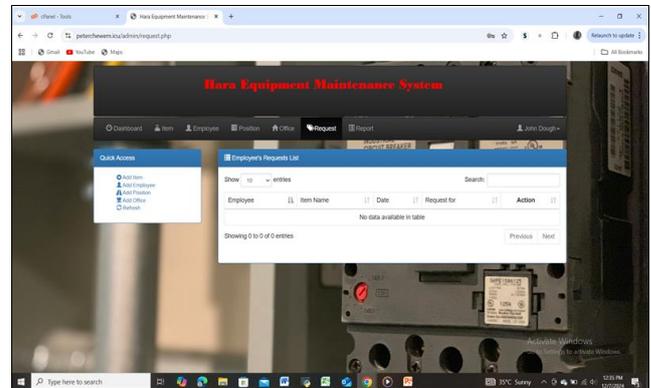

**c. Predictive Maintenance Module**

- **Purpose:** Analyse historical data to forecast potential equipment failures.
- **Algorithms:** Machine learning algorithms using historical data trends for predictive analytics.
- **Integration:** Connects with sensor data (if available) to trigger maintenance alerts before equipment fails.

**d. Inventory Management**

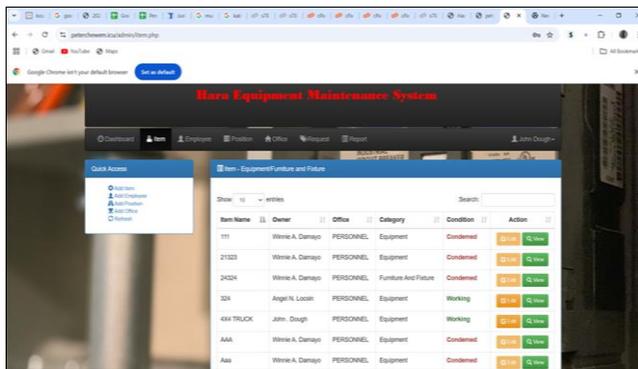

- **Purpose:** Track spare parts and consumables required for maintenance tasks.
- **Features:** Inventory levels, stock alerts, and reorder requests.
- **Database:** Updates inventory data in real time or syncs periodically in offline settings.

- **Integration Testing:** Ensure that different modules work together seamlessly.
- **System Testing:** Evaluate the complete system in a controlled environment.
- **User Acceptance Testing (UAT):** Involve actual users to test the system's functionality and usability, gathering feedback for improvements.

Source: Author

Figure: Report page

Source: Author

Figure: User interface

**Development Process**

An agile development methodology will be adopted, consisting of iterative cycles of development, testing, and refinement:

- **Phase 1: Prototype Development**
  - Develop a basic prototype focusing on core functionalities such as real-time file monitoring and logging.
- **Phase 2: Feature Integration**
  - Incorporate user authentication, unique employee details and equipment names, identification, and secure data code.
- **Phase 3: Interface Design**
  - Develop the user interface for administrators, ensuring ease of use and accessibility.
- **Phase 4: Security Enhancements**
  - Implement security features such as access controls, and secure authentication protocols.

**6. Testing and Evaluation**

Comprehensive testing will be conducted to ensure the system's reliability and effectiveness:

- **Unit Testing:** Test individual components and functions for correct operation.

**Project Timeline**

The project will be carried out over a period of six months, with the following estimated timeline:

- **Month 1:** Requirements gathering and initial system design.
- **Month 2:** Development of core functionalities.
- **Month 3:** Development of user authentication and database integration.
- **Month 4:** Implementation of the user interface and recovery mechanisms.
- **Month 5:** Testing phases, including unit, integration, and system testing.
- **Month 6:** User acceptance testing, feedback incorporation, and finalization.

**10. Resources Required**

- **Human Resources:** a software developer, a Mobile App developer and UI/UX designer.
- **Technical Resources:** Development tools, testing environments, and hardware compatible with the target operating systems. (android)

**11. Limitations**

- **Scope:** The system will focus on Windows operating systems commonly used in Zambia, and may not support other platforms initially.
- **Connectivity Challenge:** the system is design to be used in areas with less connectivity problems, hence limiting it to mining areas with total connection.

**12. Future Enhancements**

To further enhance the mining maintenance mobile application system, the following future developments are recommended:

1. **Enhanced Analytics and Reporting:** Adding advanced analytics for historical data could provide deeper insights into equipment performance, inventory usage trends, and workforce productivity, allowing for data-driven decision-making.

2. **AI-driven Predictive Maintenance:** Expanding the predictive maintenance module with machine learning algorithms would improve the system's ability to forecast equipment failures based on past performance patterns and sensor data, enabling even more proactive maintenance.
3. **Offline Capabilities:** Enhancing offline functionality for areas with limited connectivity would allow users to continue updating task statuses, logging issues, and accessing essential data, with automatic syncing when connectivity is restored.
4. **Expanded Integration with ERP Systems:** Broader integration with ERP and other business systems would enable seamless data sharing across departments, enhancing resource planning, inventory management, and maintenance budgeting.
5. **Scalability for Multi-site Management:** Developing multi-site support would allow large mining organizations to use the system across multiple locations, providing a centralized view of maintenance operations and equipment health across sites.

These future works will build on the current functionality, making the application more robust, adaptable, and efficient for broader deployment in the mining industry and beyond.

### Conclusion

The mining maintenance mobile application system has proven to be a viable solution to the inefficiencies found in traditional mining maintenance processes. The solution improves team productivity by providing real-time access to maintenance data and automating activities such as work order management and inventory tracking. Predictive maintenance capabilities, enabled by IoT data, improve equipment durability while reducing downtime. The mobile-first approach has enhanced field personnel usability and increased accessibility to maintenance workflows. This technology has shown that digital solutions may considerably improve operational effectiveness in the mining industry, making it an important tool for firms looking to upgrade their maintenance procedures.
